Sorted

Your day, sorted.

My to-do list stored everything and told me nothing

An example day before a client demo

What I typed

- Finish the demo deck by Friday 5pm
- Client call tomorrow 3 to 4
- Team sync tomorrow 3:30
- Get the slides ready for the demo
- Buy demo supplies
- Reply to the client's email

1

Two meetings overlap

The client call and the team sync clash at 3:30. A list shows them as two calm lines.

2

One job is typed twice

"Demo deck" and "slides ready" are the same work. But "buy demo supplies" is not.

3

A deadline is not a booked slot

Friday 5pm is a due time, 3 o'clock is a fixed slot. A list treats both as plain text.

So I sort it by hand, **and still have to decide what to do first.**

Sorted: type it in your own words, and it sorts it out

1

Capture

One sentence becomes a task, as a deadline, a fixed slot or a loose time window

2

Protect

Catches duplicates and overlapping meetings before saving

3

Decide

Suggests what to do next, using rules in code, not guesswork

On your phone: dashboard, Ask AI and task lists

Questions I'll answer after the demo

1

Cost

What it costs to run, today and in a release

2

Testing

How I tested it, with evidence

3

Unhandled

What I know is missing

4

Built vs configured

What is mine, what is hosted

5

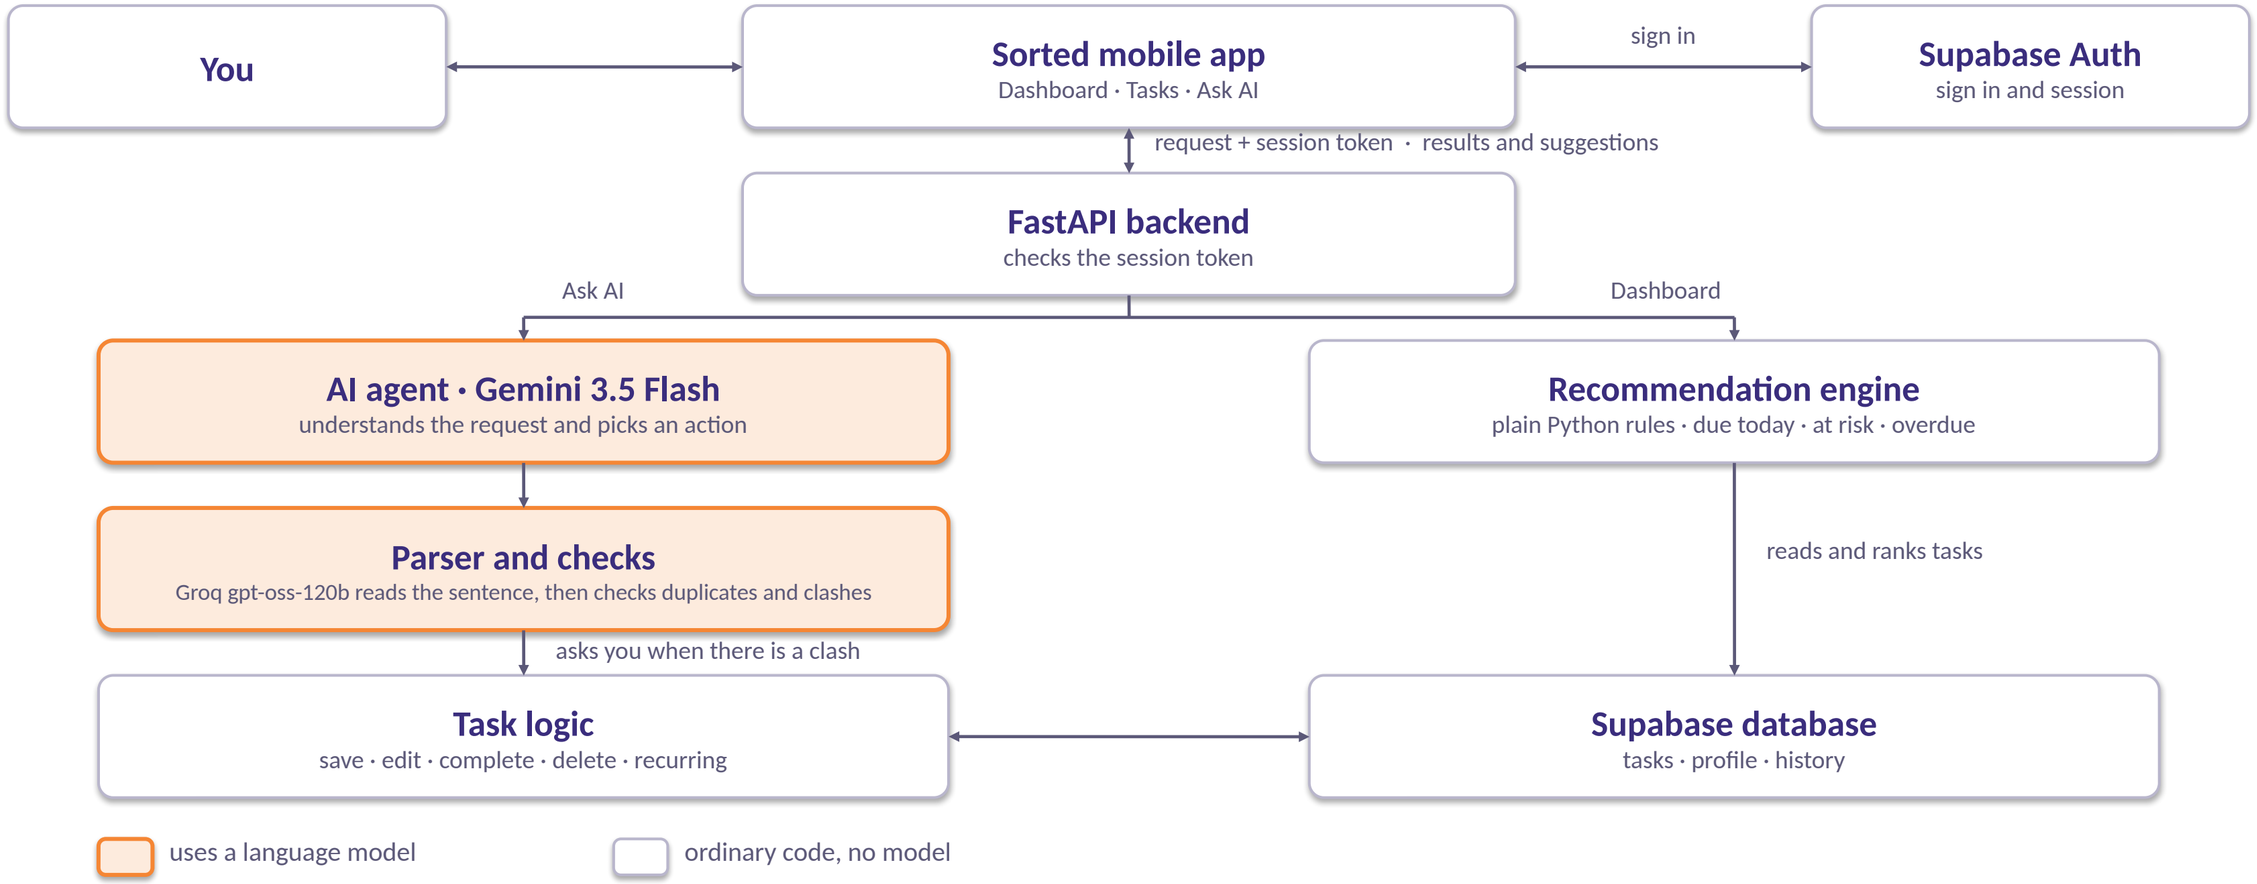

Release

What it still needs to be a product

Anything else is taken at the end.

The language model reads and explains. Code decides

What the model never does: rank tasks, detect overlapping times, or write to the database directly

What I built and what I configured

I built

- Parser prompt and checks that tell a deadline, a fixed slot and a loose window apart
- Duplicate shortlist (title and day matching) plus the judge prompt
- Overlap detection for fixed-time tasks
- Recommendation scoring: deadline slack, urgency, section weight, a window around meetings, blocked tasks excluded
- Agent tools, and the rule that deletes need a yes first
- Recurring tasks: next occurrence created on completion
- App screens and wiring to the backend

I configured or used as-is

- Supabase login and Postgres, with its row-level access rules
- Groq-hosted gpt-oss-120b (I did not train or fine-tune anything)
- Gemini 3.5 Flash for the chat layer and speech-to-text (voice has a small open bug)
- FastAPI, Expo, React Native
- rapidfuzz for fuzzy title matching

We started on Groq, hit its limit, and added Gemini

No bill so far, but only because of free tiers

Groq · gpt-oss-120b

Job: Parse each task, check duplicates (small calls)

Why: A friend said it was the fastest free option, so I started there and validated the parser on it

Gemini 3.5 Flash

Job: Chat layer: reads a message with several tasks and picks the action

Why: Groq's free tier allows about 8,000 tokens per minute and multi-task messages hit it; Gemini allows about 250,000

TODAY

$0 spent

Groq, Gemini and Supabase are on free tiers, and the backend runs on my laptop

A RELEASE NEEDS

Not priced yet

A hosted server, paid model quota, and Supabase beyond the free plan

COST PER USER

Not measured

About 3 model calls per typed task, token counts logged: calls × tokens × price

What I can show evidence for, and what is missing

Tested

98.7%

parser match against hand-labelled sentences (target was 90%)

- Every demo scene run end to end on a real account
- Two accounts on one phone: the second login showed the first user's tasks; fixed by clearing and reloading when the sign-in changes

Not tested or unhandled

- Load: no test with many users or fast repeated requests
- Questions waiting for your answer sit in server memory for 10 minutes; a restart loses them
- No queue for free-tier rate limits
- Task dependencies (do A before B) are not handled

What building this taught me

1 I didn't know how real projects run

Before this I had never used a sprint log or a backlog. Now I plan in sprints, log work daily and track planned against actual.

2 The plan didn't survive

A chatbot over a vector store and Whisper voice became a tool-calling agent and Gemini. Expecting change is part of the job.

3 My mistake: polished UI first

I should have used a throwaway screen to test the backend. Many screens changed afterwards, so that time was wasted.

4 I started knowing little

I learned how model limits work (a token cap forced a provider change), how to build a phone app, and how to run it on a phone.

What it still needs to become a product people can use

1 Make it reliable

- Fix the voice bug
- Automated tests for parser, overlap check and recommendations
- Move waiting questions into a database table
- Handle task dependencies

2 Make it safe and reachable

- Already: tokens checked on every request, own rows only, keys on the backend
- To do: HTTPS hosting, rate limiting, a review of task text sent to model providers, a dependency check
- Then: installable app, error logging, priced hosting and model quota

3 Make it useful every day

- Reminders for tasks with a fixed time

Deliberately left out: calendar sync, screenshot capture, semantic search, goal tracking. Each is new ground before the core is reliable.
